

# Chapter 1

## Basic Structure of Computers

- 1.1.
- Transfer the contents of register PC to register MAR
  - Issue a Read command to memory, and then wait until it has transferred the requested word into register MDR
  - Transfer the instruction from MDR into IR and decode it
  - Transfer the address LOCA from IR to MAR
  - Issue a Read command and wait until MDR is loaded
  - Transfer contents of MDR to the ALU
  - Transfer contents of R0 to the ALU
  - Perform addition of the two operands in the ALU and transfer result into R0
  - Transfer contents of PC to ALU
  - Add 1 to operand in ALU and transfer incremented address to PC
- 1.2.
- First three steps are the same as in Problem 1.1
  - Transfer contents of R1 and R2 to the ALU
  - Perform addition of two operands in the ALU and transfer answer into R3
  - Last two steps are the same as in Problem 1.1
- 1.3. (a)

Load	A,R0
Load	B,R1
Add	R0,R1
Store	R1,C

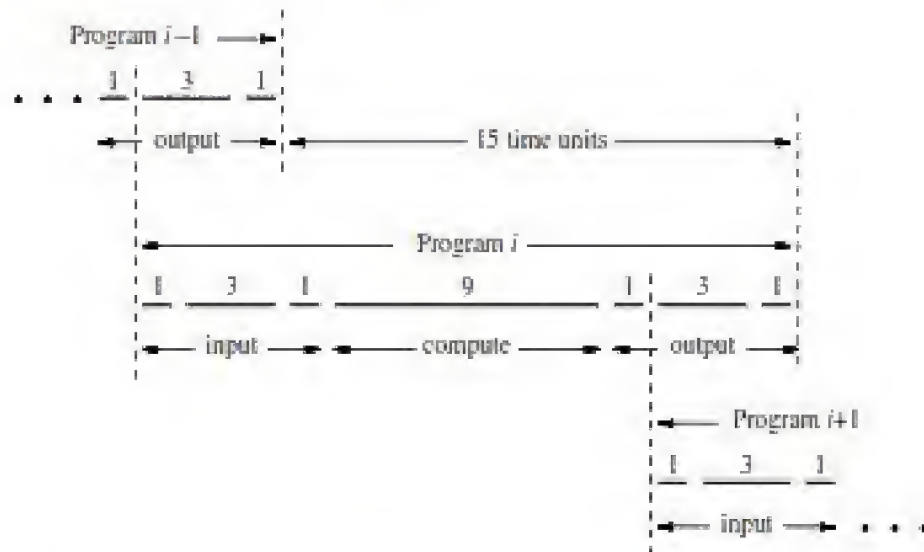

(b) Yes;

Move	B,C
Add	A,C

- 1.4. (a) Non-overlapped time for Program  $i$  is 19 time units composed as:

Overlapped time is composed as:

Time between successive program completions in the overlapped case is 15 time units, while in the non-overlapped case it is 19 time units.

Therefore, the ratio is 15/19.

(b) In the discussion in Section 1.5, the overlap was only between input and output of two successive tasks. If it is possible to do output from job  $i - 1$ , compute for job  $i$ , and input to job  $i + 1$  at the same time, involving all three units of printer, processor, and disk continuously, then potentially the ratio could be reduced toward 1/3. The OS routines needed to coordinate multiple unit activity cannot be fully overlapped with other activity because they use the processor. Therefore, the ratio cannot actually be reduced to 1/3.

- 1.5. (a) Let  $T_R = (N_R \times S_R) / R_R$  and  $T_C = (N_C \times S_C) / R_C$  be execution times on the RISC and CISC processors, respectively. Equating execution times and clock rates, we have

$$1.2 N_R = 1.5 N_C$$

Then

$$N_C / N_R = 1.2 / 1.5 = 0.8$$

Therefore, the largest allowable value for  $N_C$  is 80% of  $N_R$ .

(b) In this case

$$1.2 N_R / 1.15 = 1.5 N_C / 1.00$$

Then

$$N_C / N_R = 1.2 / (1.15 \times 1.5) = 0.696$$

Therefore, the largest allowable value for  $N_C$  is 69.6% of  $N_R$ .

- 1.6. (a) Let cache access time be 1 and main memory access time be 20. Every instruction that is executed must be fetched from the cache, and an additional fetch from the main memory must be performed for 4% of these cache accesses. Therefore,

$$\text{Speedup factor} = \frac{1.0 \times 20}{(1.0 \times 1) + (0.04 \times 20)} = 11.1$$

(b)

$$\text{Speedup factor} = \frac{1.0 \times 20}{(1.0 \times 1) + (0.02 \times 20)} = 16.7$$
